Chapter 1

Introduction

1.1 Motivation

The program will build a virtual hospital website called Smart Hospital, which aims to provide better access to medical care for residents in remote or medically underserved areas in Africa. Due to geographical limitations, transportation difficulties, and insufficient medical facilities, many residents often cannot receive good medical care. Through this virtual hospital website, residents in these areas will have the opportunity to consult with specialists remotely and receive more medical assistance and health support.

This project was initially part of a collaboration with the Africa Virtual Hospital initiative, which is dedicated to addressing healthcare disparities in remote and underserved communities across Africa. The initiative aims to connect these underserved regions with doctors and experts from around the world through its virtual hospital platform. However, despite the termination of the collaboration due to certain factors, our team chose to independently continue this project. In the context of rising global healthcare pressures, including an aging population, increasing rates of chronic diseases, and uneven distribution of medical resources, we recognize that establishing a digital healthcare website to provide telemedicine remains highly meaningful, particularly for regions with insufficient medical resources or limited access to healthcare.

1.2 Client Brief

This project was initially undertaken in collaboration with Africa Virtual Hospital. As the client, Africa Virtual Hospital proposed the development of a virtual healthcare software platform comprising the following five main components: Doctor Application, WhatsApp Chatbots for Patients and Service Providers, Caregiver Application, Nurse Application, and Electronic Health Record. Within this framework, our team's primary focus was on the doctor application, which was expected to run on multiple devices, including smartphones, tablets, and laptops. The Doctor Application component was expected to include the following elements:

- Registration
- SSO/Welcome
- Home page (Appointments and Reviews)
- Calendar (Availability)
- Notifications
- Patient Profile
- Connect (Video and Voice to Patient WhatsApp)
- Treatment Plan and Orders
- Patient Information Feed
- My Supporting Staff
- My Profile

During the collaboration period, we developed the various webpages and features of the doctor application based on the design and technical resources provided by the client. However, with the termination of the collaboration, our team also lost the original technical support. And then our new client is our University, but given the constraints on development time and resources, our team adjusted the scope based on existing resources and the original proposal, re-planned the website architecture and front-end design, and prioritized retaining core functional modules such as the doctor-patient interaction interface and basic medical information viewing, to ensure the project's feasibility under current conditions.

1.3 Aims and Objectives

The aim of this project is to design and develop an easy-to-use, cross-device virtual hospital platform to promote telemedicine and doctor-patient communication, thereby improving medical accessibility in remote areas.

Based on the aim, we have established the following specific implementation items:
Develop an intuitive user interface and create a web-based system that supports physician operations. Implement core system functions, including appointment scheduling, patient record access, and basic remote consultation workflows. Establish an integrated patient data interface to help physicians understand the patient's overall condition, thereby improving diagnostic efficiency and decision-making quality.

1.4 Challenges

This project faced three main challenges: unexpected termination of cooperation, limited development time, and difficulties in obtaining back-end data resources.

First, the project began in June and was expected to end in early September. Under the original plan, we were to collaborate with Africa Virtual Hospital to complete the development of the Doctor Application. Although most team members lacked website development experience, the development work proceeded smoothly under the guidance of Africa Virtual Hospital in the early stages.

However, the partnership was terminated prematurely in mid-July, resulting in the team losing access to technical support and shared data, and significantly compressing the remaining development timeline. With only about one and a half months left for development, the team had to independently complete tasks such as system design and construction, leading to an extremely tight schedule.

Additionally, the team had originally planned to utilize existing data from Africa Virtual Hospital, such as patient basic information and medical records. However, due to the termination of the collaboration, our backend development team faced difficulties in accessing patient data and medical records, which are highly sensitive, thereby imposing some limitations on website functionality verification and data simulation.

Despite these challenges, our team adjusted the project scope, reallocated resources, and prioritized the implementation of core functions to ensure the platform's feasibility.

Chapter 2

Background

2.1 Relative Work

In many hospitals, patients need to wait for a long time just to have a short consultation with a doctor. This can be exhausting, especially for people who are already sick. In some places like the countryside, the problem is worse because there are not enough doctors or clinics [2]. Some people need to travel very far to get help, which is hard for old people or people with long-term illness.

During COVID-19, many doctors started using phone or video to talk to patients. In the UK, it went from 15% to 48% in just a few weeks [3]. It helped people talk to doctors from home and also saved time.

Our Smart Hospital system also uses phone and video consultations. We also have Health QA, where people can ask simple health questions and get advice more easily. These help people who live far away or cannot go outside, and they also make the waiting time in hospitals shorter.

Our system supports the United Nations' SDG Goal 3, which is about helping people stay healthy and live well [4]. Among all the targets, Goal 3.8 and Goal 3.4 are especially important to our project. Goal 3.8 is about giving basic and affordable health services to everyone. Goal 3.4 is about helping people with long-term sickness, like heart disease or mental problems. Our system lets them contact doctors or get advice online more easily, so they can get help earlier before the problem becomes worse.

2.2 Existing Solutions

2.2.1 Teladoc Health

Teladoc Health is a popular online medical platform[?] that offers services like video calls with doctors and support for mental health. It is used in many countries and is helpful for people

who find it hard to go to a hospital. But one problem is that it's not fully connected to real hospitals. This means doctors on Teladoc often can't see a patient's full medical records from other clinics or hospitals. As a result, some information might be missing, which can make it harder to give the right diagnosis or follow-up care.

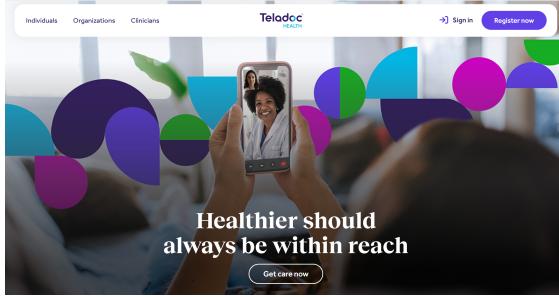

Figure 2.1: Homepage of Teladoc Health.

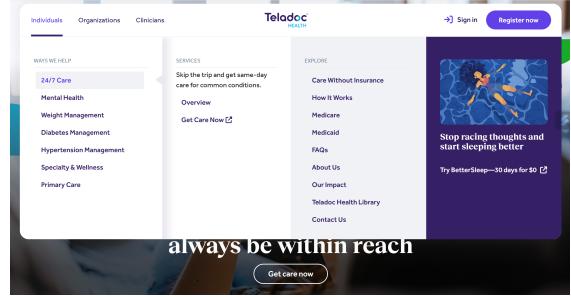

Figure 2.2: Service menu of Teladoc Health.

2.2.2 LINE Hospital Services

In Taiwan, many hospitals have their own official LINE accounts to provide online services. Patients can add the hospital's LINE to access booking and other basic functions. It is very easy to use, since most people in Taiwan already use LINE in their daily life. This makes it a common way for hospitals to offer simple medical services without asking people to download another app.

Figure 2.3: Screenshot of LINE services from Far Eastern Memorial Hospital, showing options like booking, announcements, and personal info links [1].

These features are quite easy to use. However, each hospital has its own design and menu. Some functions even open in separate websites. There is no unified system, so it can be confusing for some patients, especially older people or those not familiar with technology.

2.3 Requirements

The system is primarily designed as a web-based platform for general hospital staff, specifically doctors and nurses, to facilitate interaction with patients. The core aim is to enable healthcare professionals to manage patient information, conduct remote consultations, and reduce the need for patients to visit the hospital in person. While patients are also considered stakeholders of the system, the focus of the design and development process was placed on the needs of doctors and nurses. The decision was driven by the goal of reducing the administrative and operational workload for hospital staff, thereby improving efficiency within clinical workflows.

To ensure a functional and effective experience for hospital staff and patients, the system was designed to support a core set of features. These include secure user login and authentication for doctors and nurses, the ability to record patient vitals and view historical data trends, and an interface for remote consultation to minimise unnecessary hospital visits. As the project was developed from scratch and targeted doctors, nurses, and patients, it required the collection of foundational requirements to support the intended clinical workflow. Based on input from our original client, Virtual Hospital Africa, we analysed their existing system and designed a new solution aligned with the vision of building a smart hospital.

Non-functional requirements were also considered throughout the development process. These included ensuring a responsive and mobile-friendly user interface, maintaining data privacy through secure authentication and role-based access control, and optimising performance for minimal load times to support real-time clinical usage. These system capabilities are closely aligned with the user stories presented below.

As a...	I want...	So that...	Technical ability
Doctor	To record and view patient vitals history	I can make more accurate clinical decisions based on patient trends	3–5
Doctor	To view patient contact information	I can conduct online or follow-up appointments to discuss test results or treatments	3–5
Nurse	To input vitals data easily through a form interface	I can reduce manual paperwork and save time during rounds	2–4
Patient	To view my previous visits and vitals data online	I can better understand my health condition over time	2–3

Chapter 3

Design and Implementations

Begins a chapter. Example: When the beloved cellist (Christopher Walken - outstanding) of a world-renowned string quartet receives a life-changing diagnosis, the group's future suddenly hangs in the balance: suppressed emotions, competing egos and uncontrollable passions threaten to derail years of friendship and collaboration. Featuring a brilliant ensemble cast (including Philip Seymour Hoffman, Catherine Keener and Mark Ivanir as the three other quartet members), it is a fascinating look into the world of working musicians, and an elegant homage to chamber music and the cultural world of New York. The music, of course, is ravishing (the score is the work of regular David Lynch collaborator Angelo Badalamenti): A Late Quartet hits all the right notes.
